

Network Q&A

Q1: Using two Ethernets, when both network cables are plugged in, the PC can ping both network cards, but only unplug the ETH1 network cable, ping the IP address of ETH0 can be pinged, only unplug the ETH0 network cable, ping ETH1 IP address not working?

You can use `arp -a` on the PC side to check the arp cache table, whether the mac addresses corresponding to the two ips use eth0. If so, ping the eth0 network card that the IP address of eth1 actually goes to, so unplug the eth0 network cable and the data will not work; if not, confirm whether the next two interfaces are connected to the same network, if connected to the same network, the data will only be sent from one of them. The port goes out (the default route is eth0), and after eth1 receives the data, the response will be sent to the PC from eth0. Under normal circumstances, the purpose of connecting dual network ports in a network is to bind as a logical network card to achieve redundant backup or expand bandwidth. Otherwise, data will only be sent out from the configured default route, or the network card will be forcibly bound in the application. .
